(54) Forming Images on radiation sensitive plates

(57) A method of image formation which comprises (a) providing a radiation sensitive plate comprising a substrate and a coating containing (i) a heat softenable disperse phase, (ii) an aqueous soluble or swellable continuous phase and (iii) a radiation absorbing substance, either (i) and/or (ii) containing a reactive grouping, (b) image-wise exposing the plate to at least partially coalesce the particles of the disperse phase in the image areas, (c) developing the image-wise exposed plate to remove the coating in the unexposed areas, and (d) heating the developed plate or subjecting it to irradiation to effect insolubilisation of the image. Good quality images of high durability are obtained on the printing plate. Component (i) may be a styrene/glycidyl methacrylate copolymer so that it contains a reactive group. The exposing radiation is preferably a laser beam which is absorbed by component (ii), preferably carbon black. The plate is preferably baked after development and then optionally treated with an acidic solution of an anionic surfactant.

GB 2 273 366 A

Improvements in or relating to the formation of images

This invention relates to image formation and is concerned with the formation of images directly from electronically composed digital sources.

5 For many years it has been a long term aim in the printing industry to form printing images directly from an electronically composed digital database i.e. by a so-called "computer-to-plate" system. The advantages of such a system over the traditional methods of making printing plates are:

- 10 (i) the elimination of the costly intermediate silver film and processing chemicals;
(ii) a saving of time, and
(iii) the ability to automate the system with consequent reduction in labour costs.

15 The introduction of laser technology provided the first opportunity to form an image directly on a printing plate precursor by directing a laser beam at sequential areas of the plate precursor and modulating the beam so as to vary its intensity. In this way, radiation sensitive plates comprising a high sensitivity photocrosslinkable polymer coating
20 have been exposed to water cooled UV argon-ion lasers and electrophotographic plates having sensitivity stretching from the visible spectral region into the near infra-red region have been successfully exposed using low powered air-cooled argon-ion and semiconductor laser devices.

25 Imaging systems are also available which involve a sandwich structure which, on exposure to a heat generating infra-red laser beam, undergoes selective (image-wise) delamination and a subsequent transfer of materials. Such so-called peel-apart systems are generally used as replacements for silver halide films.

30 According to one aspect of the present invention, there is provided a radiation sensitive plate which comprises a substrate coated with:

- (i) a layer which comprises (1) a disperse phase comprising a water-insoluble heat softenable component (A) and (2) a binder or continuous phase consisting of a component (B)
35 which is soluble or swellable in aqueous, preferably aqueous alkaline, medium, at least one of components A and B

- including a reactive grouping or precursor therefor, such that insolubilisation of the layer occurs at elevated temperature and/or on exposure to actinic radiation, and
- (ii) a substance capable of strongly absorbing radiation and transferring the energy thus obtained as heat to the disperse phase so that at least partial coalescence of the coating occurs.

The plate may contain one or more of said layers and/or one or more additional layers so as to increase adhesion to the substrate, improve resistance to abrasion, or to improve the performance of the system in other respects.

The components A and B are preferably polymers and/or oligomers, at least one of which contains reactive groupings or precursors, thus providing a system in which at least one of the following conditions is fulfilled:

- a) Component A is crosslinkable;
- b) Component B is crosslinkable;
- c) Component A reacts with component B; to form a crosslinked structure;
- d) Component A is a mixture of materials A1, A2, A3, etc. which are either mutually reactive and/or react with component B;
- e) Component B is a mixture of materials B1, B2, B3, etc. which are either mutually reactive and/or react with component A.

According to another aspect of the present invention, there is provided a method of forming an image which comprises:

- (a) providing a radiation sensitive plate as hereinabove defined,
- (b) image-wise exposing the radiation-sensitive plate to a beam of high intensity radiation, by directing the radiation at sequential areas of the coating and modulating the radiation so that the particles in the coating are selectively at least partially coalesced,
- (c) developing the image-wise exposed plate with aqueous medium to selectively remove the areas containing the non-coalesced particles and leave an image on the substrate resulting from the at least partially coalesced particles, and

(d) heating the developed plate and/or subjecting it to actinic radiation to effect insolubilisation.

The substrate material used depends upon the purpose for which the image is to be used and may be, for example, formed of metal or plastics material. In the case where the image is to be used as a printing image, the substrate is preferably electrochemically treated aluminium.

The layer contains discrete domains of components A and B. The discontinuous phase A is encapsulated by the continuous phase B. The two phases A and B may form a core-shell system, as described in our earlier European Patent Application No. 92304296.4, in which case the core and shell components may be linked together via chemical bonding. Under ambient conditions, both components are preferably solid and immobile.

Component B may for example be incorporated in the composition of the invention through its use as a binder in predispersed pigmentary material added to the composition as the radiation-absorbing substance.

In practice, it is desirable to select components such that the components of the coating will not react sufficiently under normal storage conditions to hinder the imaging and development processes, but will react sufficiently rapidly at elevated temperatures to give a durable, solvent resistant image. This lack of reactivity at ambient temperature may result from the mutually reactive groups being present each in a distinct domain, so that reaction only occurs on coalescence; thus, premature reaction is effectively prevented by the use of separate phases. In the alternative, stability may be achieved by the incorporation of a system such that commencement of reaction only occurs on reaching and exceeding a specified threshold temperature.

The component A is an oleophilic polymer or oligomer, preferably having a minimum film forming temperature (MFT) above ambient temperature, and it may be an addition copolymer comprising residues derived from one or more monomers which may, by way of illustration, be selected from one or more groups from each of (i) and (ii) below:

- (i) Styrene, substituted styrenes, esters of (meth)acrylic acid, vinyl halides, (meth)acrylonitrile, vinyl esters;

- (ii) Glycidyl (meth)acrylate, allyl glycidyl ether, allyl (meth)acrylate, chloromethylstyrene, isocyanate and blocked isocyanate functional materials e.g. isocyanatoethyl methacrylate and its phenol blocked derivative, amino functional monomers e.g. dimethylaminoethyl methacrylate, acetoacetoxyethyl methacrylate, N-methylol acrylamide and its derivatives.

Alternatively, component A may be a bisphenol A epichlorohydrin epoxy resin or other suitable epoxy or polyether resin, or may be derived from a condensation polymer such as a polyester or polyurethane with (optionally blocked) reactive side or terminal groups.

The component B is preferably polymeric and contains carboxylic acid, sulphonamido, or other groups capable of conferring solubility, or at least swellability, in aqueous solutions. Particularly suitable materials for component (B) are:

- (i) copolymers derived from the copolymerisation of one or more ethylenically unsaturated carboxylic acids with one or more of styrene, substituted styrenes, (meth)acrylate esters, (meth)acrylonitrile or vinyl acetate;
- (ii) dicarboxylic acid half-esters of hydroxyl group-containing polymers, such as phthalic, succinic or maleic acid half esters of a polyvinyl acetal and, in particular, of a polyvinyl butyral; and
- (iii) alkyl or aralkyl half esters of styrene- or alkyl vinyl ether-maleic anhydride copolymers, in particular alkyl half esters of styrene-maleic anhydride copolymers such as Scripset 540 (Monsanto).

The continuous and discontinuous phases may be prepared using core-shell polymerisation techniques as described in our earlier European Patent Application No. 92304296.4, or may be obtained by simple mixing of components A and B after particle formation. The weight ratio of component B to component A may be in the range of from 1:20 to 20:1, and preferably is in the range of from 1:9 to 1:1.

The layer may be formed on the substrate using either aqueous or non-aqueous vehicles, or mixtures thereof, in order to obtain a radiation sensitive plate. It is important, however, that component A should be insoluble in the chosen vehicle or mixture.

5 In an embodiment, the source of the high intensity radiation is a laser operating in the ultra-violet, visible or infra-red region of the spectrum. Red and infra-red light emitting lasers are preferred, for example the semiconductor or diode lasers typical of which is the gallium aluminium arsenide laser which operates in the 750-870 nm
10 region.

 The radiation-absorbing substance may be present in the same layer or layers as components A and B, or it may be present in a separate but adjacent layer. Examples of suitable laser radiation absorbing substances are carbon black and graphite and phthalocyanine, croconium
15 and squarylium type dyestuffs.

 The radiation-absorbing substance is present in an amount which is effective to cause some coalescence of the coating under the influence of the high intensity radiation. Generally, the radiation absorbing substance will constitute from 2.0 to 80%, by weight, of the coating.

20 Preferred developers for selectively removing the non-coalesced material in the non-image areas are aqueous alkalis, such as solutions of ethanolamine and sodium metasilicate, an alkaline phosphate such as sodium phosphate, or an alkali metal hydroxide in water.

 The following examples illustrate the invention:

25 **EXAMPLE 1**

 To a 500 ml flanged flask equipped with condenser, mechanical stirrer, and N₂ inlet/exit was charged 250 ml of distilled water, 1.5 g of sodium lauryl sulphate and 0.75 g of ammonium persulphate. The temperature was raised to 70°C and a nitrogen blanket was applied.
30 71.2 g of styrene and 3.744 g of glycidyl methacrylate were mixed together and pumped into the aqueous surfactant solution so that the addition took 1½ hours.

 The pump was washed through with 50 ml of distilled water and the mixture was maintained, with stirring under N₂ at 70°C for a further two
35 hours.

The resultant latex had a monomer content of $< 0.01\%$ a particle size < 300 nm and a solids content of 20%.

50 g of an 8% w/w solids content coating mixture was prepared from 12 g of the polymer dispersion

5 9.75 g of a 16.4% solids Microlith Black CWA dispersion (prepared by stirring Microlith Black CWA pigment (a carbon black pigment) from Ciba Geigy Pigments, Manchester UK with H_2O /Isopropanol and then adding ammonia)

13.25 g distilled water

10 15 g IPA (isopropyl alcohol)

and was coated onto a grained and anodised aluminium substrate to give a coat weight of 0.9 gm^{-2} . In this case, component A was a styrene/glycidyl methacrylate copolymer and component B was the alkali-soluble binder associated with the carbon black pigment. The plate was
15 exposed by an array of 32 x 100 mW laser diodes (Creo Products Inc. Burnaby, Canada) at a nominal 10 micron beam width giving an exposure of 130 mJcm^{-2} , to effect at least partial coalescence of the particles in the layer in the radiation-struck areas.

A very high quality image was obtained after development in a
20 sodium metasilicate based developer (Unidev, from DuPont Howson) to remove the non-coalesced areas of the layer.

The plate was baked for two minutes at 200°C , then finished with an acidified solution of an anionic surfactant (Unifin, from DuPont Howson). The plate had developed good resistance to solvents such as
25 toluene and 1-methoxy-2-propanol and give in excess of 100,000 copies on a web offset press.

The obtained plates were very stable on storage, i.e. they could still be imaged and decoated many months after preparation. The baking response was not diminished significantly.

30 EXAMPLE 2

The above sample was repeated except that 3 g of bromotrichloromethane was added to the monomers before the addition. Excellent image quality and solvent resistance was again obtained.

EXAMPLE 3

In a 500 ml flask equipped as in Example 1 were placed 43 ml of Carboaset XL37 (alkali soluble carboxylated acrylic resin, available from B.F Goodrich, 35% solids dispersion). 200 ml of distilled water and
5 10 ml of 25% NH_3 were added and the mixture was stirred until clear. 0.9 g ascorbic acid and 1.48 g of potassium persulphate were added.

A mixture of styrene (71.21 g), glycidyl methacrylate (3.744 g) and bromotrichloromethane (3 g) was added and the temperature raised to 35°C under an atmosphere of nitrogen. The temperature was maintained at 35°C
10 for seven hours. A fine particle size latex of low monomer content was obtained. The solids content was 25% w/w.

A 9% solids dispersion was prepared by mixing 21.6 g of the above dispersion with 21.95 g of a 16.4% Microlith Black CWA dispersion. 6.45 g of H_2O and 50 g IPA were added to the mixture which was then
15 coated onto a grained and anodised aluminium substrate to give a coat weight of 0.9 gm^{-2} . In this case, component A was a styrene/glycidyl methacrylate copolymer, and component B was the combination of the carboxylated acrylic resin associated with component A as the shell material, and the alkali-soluble binder associated with the carbon black
20 pigment. The plate was exposed as in Example 1 to give an excellent image which after baking at 200°C for two minutes gave greater than 100,000 impressions on a web offset press. The plates were stable on storage and the baking response was not diminished after many months.

EXAMPLE 4

25 414 ml of distilled water were placed in a 2 l flask equipped with stirrer, condenser, thermometer and N_2 inlet/exit. To the stirred water were added 85.8 ml of Carboaset XL37. Then 16 ml of 25% aqueous ammonia were added. When a crystal clear solution was obtained, 150 g of styrene were added, followed by 1.5 g of ammonium persulphate in 10 ml
30 distilled water. The mixture was maintained at 65°C with vigorous stirring for a period of four hours to give a final product of solids content 25% w/w, with a particle size of less than 0.5 microns and a residual monomer content of 0.05% w/w. The final product was a core-shell dispersion composed of particles comprising a core of polystyrene
35 and a shell of the carboxylated acrylic copolymer.

12 g of the core shell dispersion was mixed with 12.2 g of a 16.4% w/w Microlith Black CWA dispersion, 0.5 g Cymel 300 (Hexamethoxy methyl melamine from Cyanamid), 2.25 g distilled water and 25 g of IPA. The material was coated to give a 0.9 gm^{-2} layer on a grained and anodised aluminium substrate. In this instance, component A was polystyrene, and component B was the combination of the carboxylated acrylic resin associated with component A as the shell material, and the binder associated with the carbon black pigment. The plate was exposed as in Example 1 and decoated with an aqueous solution of monoethanolamine (Electrosol 85, from DuPont Howson) and baked for two minutes at 200°C . A very good quality image was obtained which showed exceptional solvent resistance. The plate could not be decoated after one day storage.

EXAMPLE 5

414 cm^3 of distilled water was placed in a 2l flask equipped as in Example 1.

85.8 cm^3 of Carboset XL37 and 16 cm^3 of 25% aqueous ammonia was added to the stirred water. When a clear solution was obtained 130 g of styrene, 20 g of Cylink IBMA Monomer (N-(isobutoxy-methyl)acrylamide - supplied by American Cyanamid Company, Wayne, New Jersey) and 6 g of bromotrichloromethane were added as a mixture. 1.5 g of ammonium persulphate in 10 cm^3 of water was added and the mixture was stirred for six hours at 65°C under an atmosphere of nitrogen.

50 g of a coating solution was prepared by adding

- 11 g of the above dispersion
- 11 g of 16.4% w/w Microlith Black CWA
- 15.5 g distilled water
- 12.5 g of IPA

and coated on a grained and anodised aluminium substrate to give a coat weight of 0.9 gm^{-2} . In this example, component A was a copolymer of styrene and N-(isobutoxymethyl)acrylamide, and component B was the combination of the carboxylated acrylic resin associated with component A as the shell material, and the binder associated with the carbon black pigment. The plate was exposed as in Example 1 and decoated with a sodium metasilicate-based developer to give an excellent quality image. After baking the material for two minutes at 200°C the solvent resistant

image was gummed and gave excellent durability when used on a web offset press.

The plates were storage stable and the baking response of imaged and decoated plates was not significantly diminished after many months storage.

EXAMPLE 6

Example 1 was repeated but the monomer mixture was now 7.5 g of Cylink IBMA and 67.5 g of styrene. Thus, component A in this case was a copolymer of styrene and N-(isobutoxymethyl)acrylamide, and component B was the alkali-soluble binder associated with the carbon black pigment. Excellent results were obtained.

EXAMPLE 7

Example 1 was repeated except that 3 g of Bisomer SEM (ammonium sulphate ethyl methacrylate aqueous solution from BP Chemicals) was added. Components A and B were thus as in Example 1, but the incorporation of this reactive copolymerisable surfactant improved the colloidal stability of the latex - especially to alcohol additions and to coating aids.

EXAMPLE 8

A blocked isocyanate was prepared by reacting methyl ethyl ketone oxime with isocyanatoethyl methacrylate in anhydrous toluene.

10 g of the purified adduct were copolymerised with 65 g of styrene under identical conditions to those used in Example 1.

A 20% solids dispersion of the polymer was obtained.

A pigment dispersion was prepared by ball milling the following materials for forty hours

	Acrylsol I-62 (hydroxy and carboxy functional acrylic resin as aqueous colloidal dispersion, 50% solids, available from Rohm and Haas, Philadelphia)	40 g
30	FW2 carbon black (Degussa)	20 g
	Triethylamine	4 g
	Distilled Water	250 g

A coating was prepared from a dispersion consisting of

13.5 g of the latex as prepared above

14 g pigment dispersion as prepared above

10 g distilled water

5 12.5 g IPA

This was coated on to a grained and anodised substrate to give a coat weight of 0.9 gm^{-2} . In this example, component A was a copolymer of styrene and the methyl ethyl ketone oxime/isocyanatoethyl

10 methacrylate adduct, and component B was the hydroxy and carboxy-functional acrylic resin.

After exposing as in Example 1 an excellent image was obtained. The image was highly solvent resistant after baking for two minutes at 200°C .

EXAMPLES 9-15

15 Examples 1-7 were repeated except that an equivalent amount of the Acrysol I-62 stabilised carbon black was used in place of Microlith Black CWA, with the consequent effect on the composition of component B. Excellent results were obtained.

EXAMPLES 16-17

20 Examples 1 and 2 were repeated except that half of the styrene was replaced by methyl methacrylate producing a styrene/methyl methacrylate/glycidyl methacrylate copolymer as component A. Good results were obtained.

EXAMPLE 18

25 A solution of SQS (squarylium dye) in IPA was used in conjunction with the core shell latex of Example 3. Good results were obtained. The SQS acted as the IR absorbing component and was prepared as described in US Patent 4,508,811.

35

CLAIMS

1. A method of forming an image which comprises:
 - 5 (a) providing a radiation sensitive plate which comprises a substrate coated with:
 - (i) a layer which comprises (1) a disperse phase comprising a water-insoluble heat softenable component A and (2) a binder or continuous phase consisting of a
10 component B which is soluble or swellable in aqueous, preferably aqueous alkaline, medium, at least one of components A and B including a reactive grouping or precursor therefor, such that insolubilisation of the layer occurs at elevated temperature and/or on
15 exposure to actinic radiation, and
 - (ii) a substance capable of strongly absorbing radiation and transferring the energy thus obtained as heat to the disperse phase so that at least partial coalescence of the coating occurs.
 - 20 (b) image-wise exposing the radiation sensitive plate to a beam of high intensity radiation, by directing the radiation at sequential areas of the coating and modulating the radiation so that the particles in the coating are selectively at least partially coalesced,
 - 25 (c) developing the image-wise exposed plate with aqueous medium to selectively remove the areas containing the non-coalesced particles and leave an image on the substrate resulting from the at least partially coalesced particles, and
 - 30 (d) heating the developed plate and/or subjecting it to actinic radiation to effect insolubilisation.

2. A method as claimed in claim 1 wherein components A and B form a core-shell system.
3. A method as claimed in claim 1 wherein component A comprises one or more oleophilic polymers or oligomers, at least one of which
5 contains reactive groupings or precursors.
4. A method as claimed in claim 3 wherein component A comprises one or more addition copolymers comprising residues derived from one or more monomers selected from each of:
 - (i) styrene, substituted styrenes, esters of (meth)acrylic
10 acid, vinyl halides, (meth)acrylonitrile, vinyl esters; and
 - (ii) glycidyl (meth)acrylate, allyl glycidyl ether,
allyl(meth)acrylate, chloromethylstyrene, isocyanate and
blocked isocyanate functional materials, amino functional
monomers, methacrylamido glycolate methyl ether, N-methylol
15 acrylamide and its derivatives.
5. A method as claimed in claim 3 wherein component A comprises an epoxy or polyether resin, or a derivative of a polyester or a polyurethane resin.
6. A method as claimed in claim 1 wherein component B comprises a
20 polymer containing groups capable of conferring solubility or swellability in aqueous solutions.
7. A method as claimed in claim 6 wherein component B contains carboxylic acid or sulphonamido groups.
8. A method as claimed in claim 7 wherein component B comprises a
25 copolymer derived from the copolymerisation of one or more ethylenically unsaturated carboxylic acids with one or more of styrene, substituted styrenes, (meth)acrylate esters, (meth)acrylonitrile or vinyl acetate.
9. A method as claimed in claim 7 wherein component B comprises a
30 dicarboxylic acid half-ester of a hydroxyl group containing polymer.

10. A method as claimed in claim 7 wherein component B comprises a phthalic, succinic or maleic acid half ester of a polyvinyl acetal.
11. A method as claimed in claim 10 wherein the polyvinyl acetal is polyvinyl butyral.
12. A method as claimed in claim 7 wherein component B comprises an alkyl or aralkyl half ester of a styrene or alkyl vinyl ether-maleic anhydride copolymer.
13. A method as claimed in claim 1 wherein the weight ratio of component B to component A is in the range of from 1:20 to 20:1.
14. A method as claimed in claim 1 wherein the weight ratio of component B to component A is in the range of from 1:9 to 1:1.
15. A method as claimed in claims 1-14 wherein the substrate comprises a metal or plastics material.
16. A method as claimed in claim 15 wherein the metal is electrochemically treated aluminium.
17. A method as claimed in claim 1 wherein the radiation absorbing substance comprises carbon black, graphite or phthalocyanine, croconium or squarylium type dyestuffs.
18. A method as claimed in claim 1 wherein the source of the high intensity radiation is a laser operating in the ultra-violet, visible or infra-red region of the spectrum.
19. A method as claimed in claim 18 wherein the laser is a gallium aluminium arsenide laser.
20. A printing plate obtained by the methods as claimed in any of claims 1-17.
21. A method of forming an image substantially as hereinbefore described and with reference to any of the Examples.
